Subject: Smoky Canyon Mine Remedial Investigation/Feasibility Study
Dinwoody Material Source Investigation Report

Dear Art,

Attached for your review is the *Dinwoody Material Source Investigation Report* for your review. The J.R. Simplot Company (Simplot) is providing this final information in accordance with the August 2009 Settlement Agreement/Consent Order, as part of the Remedial Investigation/Feasibility Study (RI/FS) conducted under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA).

| ***Re:*** | **Dinwoody Material Source Investigation Report** |

The objective of this investigation is to provide site-specific information needed for the detailed analysis of remedial alternatives in the FS by locating, delineating, and estimating available volumes of Dinwoody material for potential future use. The potential borrow sources investigated for further evaluations included B-Panel A & B, West Smoky C, D-Panel A & B, and E-Panel A & B. **Figure 1** shows the areas included in this investigation.

Dinwoody Formation is visibly present in the constructed road cuts and pads; however, the material type varies from site to site. Excavations at each site varied in depth and were limited by either material type or equipment reach. Photo documentation is provided for cuts, pads, and excavations at the sites. It should also be noted that the cut associated with constructing access to sites is included in determining material thickness. Site specific descriptions included logging the differences between Type A, Type B, and unsuitable Dinwoody material will be indicated by changes in color, clay content, field durability testing, and test pit excavation equipment behavior.

**Volume Estimates**

Distinct characteristics and variable weathering make each dig location unique. Because of a lack of homogeneity a simplified approach to calculating potential volumes of recoverable Dinwoody was employed. Each area was looked at as a whole to determine the depth of topsoil to be removed and appropriate depth of extractable material or refusal. Depth and area are the controlling factors determined by the excavations, while borrow designs were standardized 2:1 cuts from surface without attention to drainage or other slope stability considerations.

The areas involved in the calculations were based on the original delineated borrow areas but modified based on field observations. Volumes are not indicative of material quality but signify the amount of material in the area that appears to be available for excavation. **Table 1** includes updated areas and volumes for the borrow areas along with a description of the material type cover suitability.

**B-Panel Borrow Area**

Documentation for each excavation site and any other field observations are in the trench logs attachment. B-Panel borrow contained excellent clay rich material overall. All excavations in this area were extended to the maximum reach of the equipment. Site DW_BB02 had some less desirable gravely zones near the surface and has been adjusted to the edge of the borrow area. **Figure 2** indicates the areas of the original B-Panel borrow designs and the new adaptations following examinations from this field program. Selected images for each site are included in this report, additional photo documentation is available within the attachments.

Volumes in this area were updated anticipating removal of 4 feet of topsoil with an overall 30 foot deep excavation below topography. Good material likely exists deeper as the termination of the excavations were in good clay material at the bottom.

**West Smoky C Borrow Area**

Overhead and buried power lines extend the entire length of the proposed borrow site therefore it was not evaluated.

**D-Panel Borrow Area**

All sites were terminated at refusal of digging and ripper teeth were broken on the rock at sites DA01 and DA03. Although none of the excavation sites indicated good quality Dinwoody cover material, road cuts were considered in evaluation of the site as a whole. Additional field notes for the D-Panel borrow areas and excavation sites are in the trench logs attachment. A general observation in the steep D and E panel areas is that there is more cliff forming rock with elevation up the slope. **Figure 3** indicates the areas of the original D-Borrow designs and the adaptations following examination from this field program. Selected images for each site are included in this report and additional photo documentation is available within the attachments.

Volumes in this area were updated within a much smaller areas. Calculations within this area assumed 3 feet of topsoil and 10 feet total depth for excavating material below topography. Despite the conservative estimate, it is still unlikely that all the area that could be excavated would be suitable for cover material.

**E-Panel Borrow Area**

All sites were terminated at refusal of digging through rock. EA01 and EB02 were completed nearly at the surface. None of the excavation sites indicated a large quantity of good cover-quality Dinwoody. Alternating rock and loose material in some locations saw better digging below the surface rock outcrops although none or the trenches were extended to the reach of the equipment before refusal. The upslope extent for accumulation of usable, weathered Dinwoody appears to coincide with the areas of existing borrows in both D and E panel. Additional field notes for the E-Panel borrow excavation sites are in the trench logs attachment.

**Figure 4** indicates the areas of the original E-Borrow designs and the adaptations following examinations from this field program. Selected images for each site are included in this report with additional photo documentation available within the attachments.

Volumes in this area were updated within a much smaller areas. Calculations within this area assumed 3 feet of topsoil and 15 feet total depth for excavating material below topography. Most of this material would not be suitable for cover material.
